NASA Goddard Institute for Space Studies

AGCI ESM Evaluation Workshop

August 3rd, 2017

Effects of climate change on agricultural prices (2050 RCP8.5 relative to results without climate change in 2050)

Source: Model results as of February 15, 2013

Note: All changes relative to the reference scenario for the same year.

AgMIP Global Economics Model Intercomparison
10 Global Economics Models, 2 GCMs, 2 crop models
Von Lampe et al., *Agricultural Economics*, 2013
Baseline from SSP2

Uncertainty for Global Prices: Economics Models > Crop models > Climate models

ESM evaluation provides physical confidence in model outputs that are at the heart of applications

Societal impact applications are most concerned with:

- Direct evaluation of a relatively small subset of near-surface 2D fields that are of primary interest
- Understanding of these variables' changing distributions
- Indicators of performance and proxies for primary variables of interest
- Stakeholders' own backyards

Outline

The VIACS Community of ESM output users

²Columbia University Center for Climate Systems Research

³Climate Service Center, HZG, Hamburg

Vulnerability, Impacts, Adaptation

Charged with understanding how climate changes affect natural and human systems (largely basic research)

➤ VIA Sectors:

- Agriculture
- Forestry
- Energy
- Water Resources and Hydrology
- Oceans/Fisheries
- Coastal
- Biomes/Ecology
- Urban
- Health
- Infrastructure/Transportation

➤ Projects and Programs:

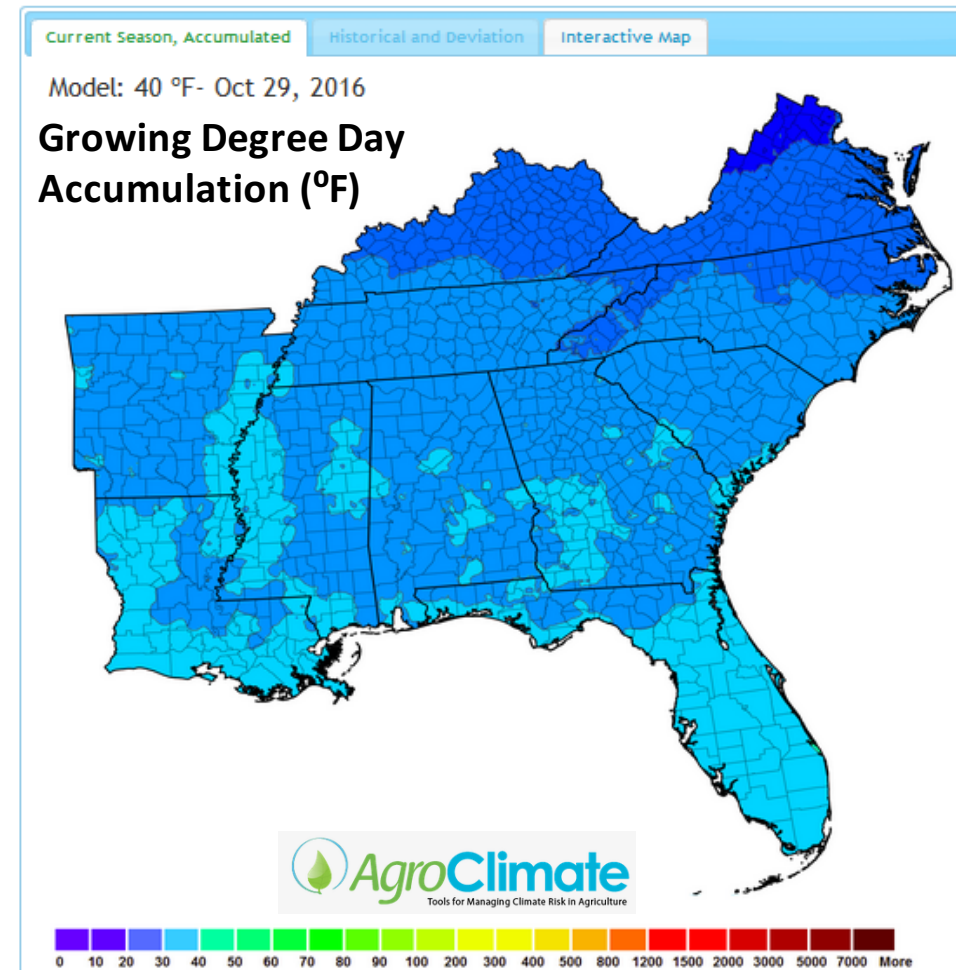

- TGICA, CORDEX, ICONICS
- WCRP Working Group on Regional Climate
- ISI-MIP, AgMIP, WaterMIP
- Others...

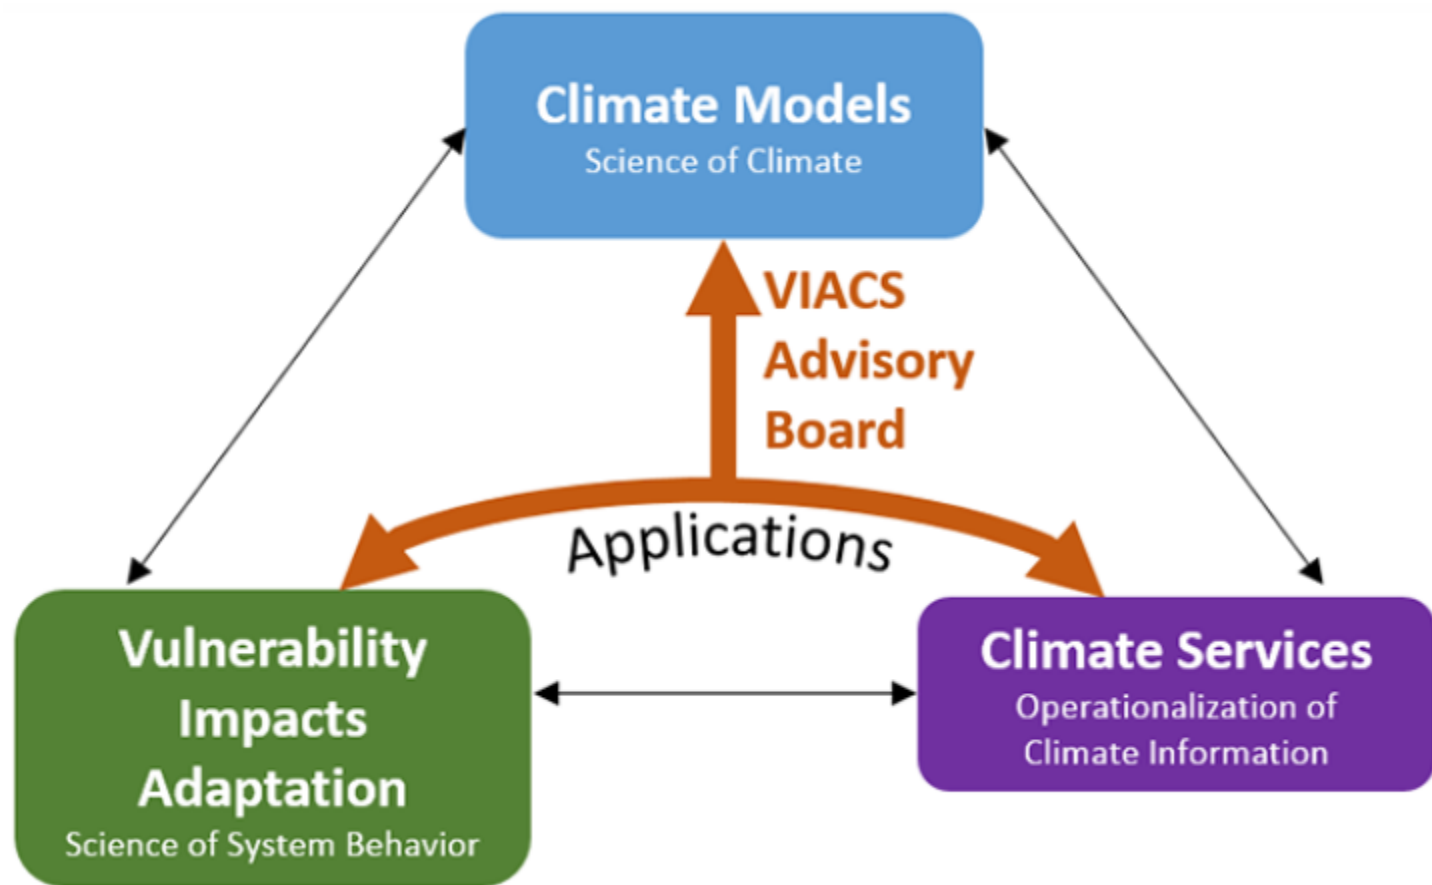

Climate Services

Operationalizes climate and VIA information as user-oriented products and tools.

- **Climate Service Organizations:**
 - Public Agencies
 - Private Organizations
 - Academic Institutions
- **Projects and Programs:**
 - Climate Services Partnership
 - Global Framework for Climate Services
 - Others...

VIACS Advisory Board Members

| Name | Community | Institution |
|----------------------------|--------------------------|---|
| Alex Ruane (co-chair) | <i>Agriculture/AgMIP</i> | NASA Goddard Institute for Space Studies, USA |
| Claas Teichmann (co-chair) | <i>Climate Services</i> | Climate Service Center, Hamburg, Germany |
| Nigell Arnell | <i>WaterMIP</i> | University of Reading, UK |
| Tim Carter | <i>TGICA</i> | Finnish Environment Institute (SYKE), Finland |
| Kristie Ebi | <i>ICONICS/Health</i> | University of Washington, USA |
| Katja Frieler | <i>ISI-MIP</i> | Potsdam Institute for Climate Impacts Research, Germany |
| Clare Goodess | <i>WGRC</i> | University of East Anglia, UK |
| Bruce Hewitson | <i>CORDEX</i> | University of Cape Town, South Africa |
| Radley Horton | <i>Urban/Coastal</i> | Columbia University, USA |
| Sari Kovats | <i>Health</i> | London School of Hygiene and Tropical Medicine, UK |
| Heike Lotze | <i>Oceans/Fisheries</i> | Dalhousie University, Canada |
| Linda Mearns | <i>ICONICS</i> | National Center for Atmospheric Research, USA |
| Antonio Navarra | <i>Climate Services</i> | Istituto Nazionale di Geofisica e Vulcanologia, Italy |

- **Motivation, initial activities, and plans for VIACS Advisory Board**

VIACS Advisory Board Engagement with CMIP6 Variable Design

900+ CMIP5 Variables assessed for VIACS applications

- Necessary variables for most applications already exist
- Determined priorities – strong desire for more validation and quality assessment studies
- Identified complete sets needed to allow particular applications (e.g., ocean ecosystems requires many unique variable sets)
- Variables queued up for download from the CMIP6 Data Request according to community (e.g., several AgMIP packages)

| | | | | Variable Set Requests/Categorization | | | |
|--|-----------------|--|------------|--------------------------------------|-----|--------|----------|
| | | | | AgMIP | CSP | Arctic | FISH-MIP |
| Variable Category | Time Resolution | Long Name | Units | | | | FISH-MIP |
| 2(e) Monthly land biogeochemistry, soil and land cover data | | | | | | | |
| CMOR Table Lmon: Monthly Mean Land Fields, Including | | | | | | | |
| Physical, Vegetation, Soil, and Biogeochemical Variables | | | | | | | |
| @Lmon | monthly mean | Moisture in Upper Portion of Soil Column | kg m-2 | 2 | 2 | 0 | 0 |
| | monthly mean | Total Soil Moisture Content | kg m-2 | 1 | 1 | 0 | 0 |
| | monthly mean | Soil Frozen Water Content | kg m-2 | 2 | 2 | 0 | 0 |
| | monthly mean | Surface Runoff | kg m-2 s-1 | 2 | 2 | 0 | 0 |
| | monthly mean | Total Runoff | kg m-2 s-1 | 2 | 2 | 0 | 2 |
| | monthly mean | Precipitation onto Canopy | kg m-2 s-1 | 3 | 3 | 0 | 0 |
| | monthly mean | Evaporation from Canopy | kg m-2 s-1 | 3 | 3 | 0 | 0 |
| | monthly mean | Water Evaporation from Soil | kg m-2 s-1 | 3 | 3 | 0 | 0 |
| | monthly mean | Transpiration | kg m-2 s-1 | 3 | 3 | 0 | 0 |
| | monthly mean | Water Content of Soil Layer | kg m-2 | 1 | 1 | 0 | 0 |
| | monthly mean | Temperature of Soil | K | 3 | 3 | 1 | 0 |
| | monthly mean | Tree Cover Fraction | % | 4 | 4 | 0 | 0 |
| | monthly mean | Natural Grass Fraction | % | 4 | 4 | 0 | 0 |

VIACS Advisory Board Engagement with CMIP6 Variable Design

60+ new variables requested (and more continuously coming in)

- Requirement of different time periods or heights
- Need for low-frequency reports of high-frequency statistics, e.g.:
 - monthly output file showing number of hours where precipitation exceeded a given heavy rain threshold
 - separation of variables by wet and dry days
- Interest in tile information, if simulated (e.g., agricultural tile of broader grid box)

Photo: constructionweekonline.com

| Time resolution | Name (plus description as needed) | Units | Additional notes |
|---|---|-----------------------------------|---|
| New variables requested by the agricultural sector (for Historical, DECK, and ScenarioMIP experiments, as well as requests for experiments within AerChemMIP, C ⁴ MIP, DAMIP, DCP, GeoMIP, LUMIP, and VolMIP). | | | |
| Monthly | Surface concentration of ozone | ppm | Also for use ecosystem and health sectors |
| Daily, monthly | Cropland tile maximum temperatures | K | Tile contains information from agricultural |
| Daily, monthly | Cropland tile minimum temperatures | K | fraction of land in a given GCM |
| Daily, monthly | Cropland tile precipitation | $\text{kg m}^{-2} \text{ s}^{-1}$ | grid box. |
| Daily, monthly | Cropland tile minimum relative humidity | % | |
| Daily, monthly | Cropland tile wind speed | m s^{-1} | |
| Monthly | Number of precipitation days where accumulation was above 1 kg m^{-2} | No. | These two variables combine to describe the intensity of rainfall when it does occur. |
| Monthly | Average precipitation accumulation on days where accumulation was above 1 kg m^{-2} | kg m^{-2} | |

VIACS Advisory Board Engagement with CMIP6 MIP Application

188 MIP Experiments assessed for VIACS applications

- Determined priorities for various application packages
- Identified specific experiments within MIPs that VIACS community is interesting in exploring for broader implications
- Historical and ScenarioMIP experiments most widely sought, followed by Decadal Climate Prediction Project (DCPP) and HighResMIP
- Nearly all MIPs had at least one experiment that generated VIACS interest

| CMIP6 MIP Experiments that you plan on exploring (see full names of MIPs in next tab): | | | | | | AgMIP |
|--|-----------------------|--|-----|---|--|-----------|
| Experiment group | Experiment short name | Experiment Description / Design | | | | |
| @EXPT | | | 188 | | | |
| Diagnostics, Evaluation, and Characterization of Klima (DECK)-1 | AMIP | observed SSTs and sea ice prescribed | 24 | 0 | | 1,2,3 |
| DECK-2 | control | coupled atmosphere/ocean pre-industrial control run | 26 | | | 1,2,3 |
| DECK-3 | 1pctCO2 | impose 1%/yr increase in CO2 to quadrupling* | 25 | | | 1 |
| DECK-4 | abrupt4xCO2 | Abruptly quadruple CO2, then hold fixed** | 24 | | | 1 |
| DECK-5 | historical | emission- or concentration-driven simulation of the recent past (~165 years) | 26 | | | 1,2,3,4,5 |
| AerChemMIP-1 | RFDOC-01 | Perturbation from 1850 control using PD aerosol and ozone precursor emissions (all aerosols interact with radiation) | 23 | | | 1, 5 |
| AerChemMIP-1 | RFDOC-02 | Perturbation from 1850 control using PD aerosol and ozone precursor emissions (only BC aerosols interact with radiation) | 21 | | | 0 |

Understanding Stakeholder Needs

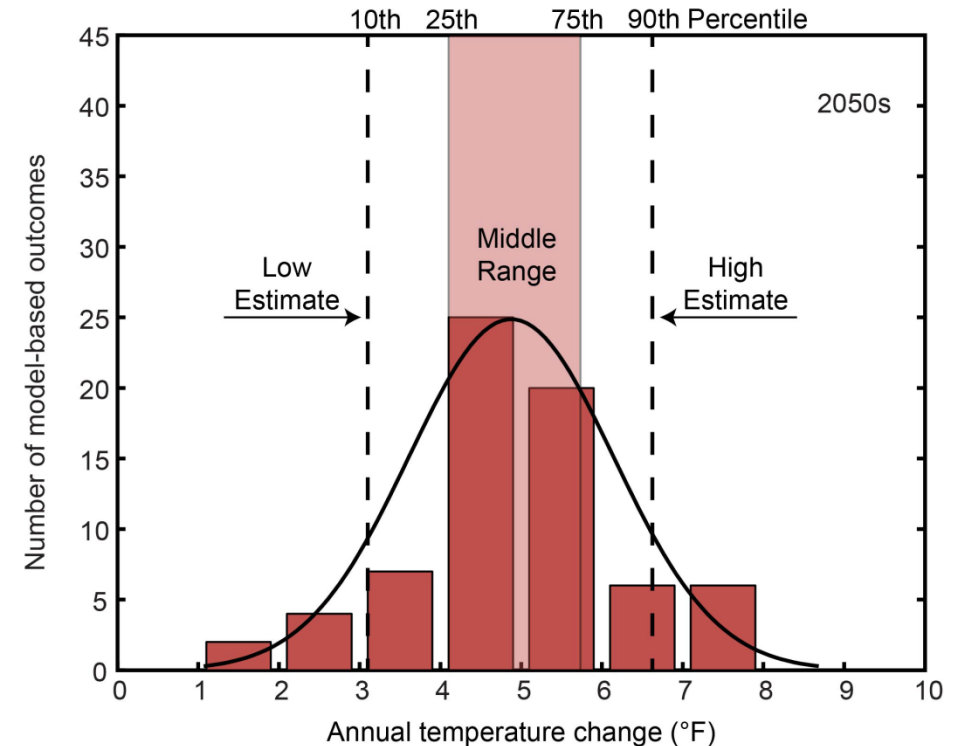

DRAFT-Temporal Scale of Agricultural Sector Stakeholder Interest

Stakeholders want:

- Credibility of climate data established in observational period
- Highest possible resolution (*must be connected to value of added detail*)
- Single answer (*but accepting of probabilistic information for risk management framework*)
- Basic understanding of process used to make scenarios
- Sustained engagement

Model-based range of outcomes (distribution) for 2050s temperature change in New York City relative to the 1971 - 2000 base period. Based on 35 global climate models and 2 representative concentrations pathways. The 10th, 25th, 75th, and 90th percentiles of the distribution are presented.

New York City Panel on Climate Change, 2013

Climate Risk Information:

- Start with the questions: “When has climate or weather affected you in the past? What changes in climate do you notice in recent years?”
- Characterize in current system
- Project changes in future system
- Envision future changes in climate (including new threats) and place in context of socioeconomic development and technological change

Huge diversity in tailored metrics requested

- E.g., chill hours for blueberries, killing degree days for wheat, consecutive dry days, extreme temperatures for airport runway closure, critical overwinter temperatures for pests, temperature-humidity indices for health, heavy downpours for flash flooding, wind speed at turbine height...
- Most are statistics or close derivatives of temperature, rainfall, wind, humidity, and precipitation distributions

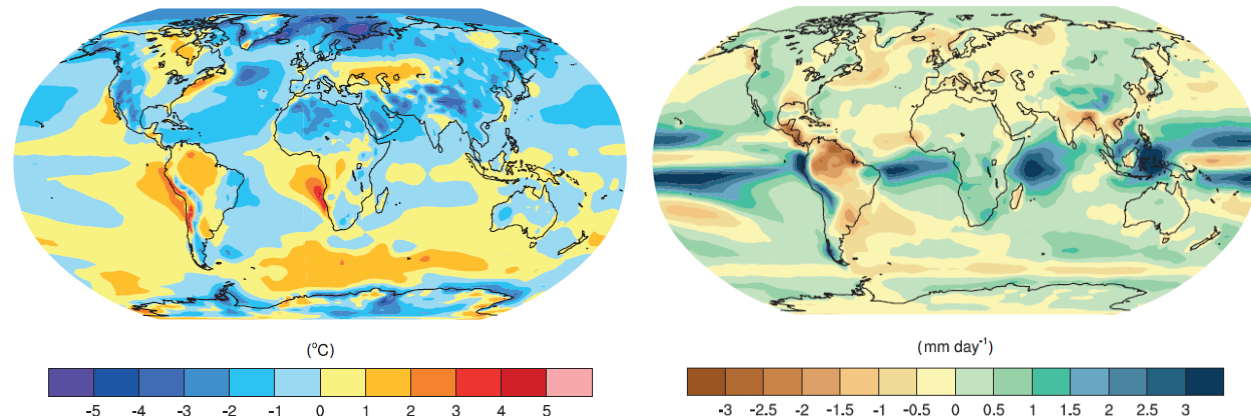

How ESM Outputs are Often Applied

Raw ESM output rarely used directly for VIACS analysis due to resolution, biases, sampling of internal variability, and efficiency

ESM outputs are often evaluated through the following lenses:

- Further downscaling
(dynamical or empirical)
- Bias-correction / scenario generation
(depends heavily on change statistics and target observational dataset)
- Weather generators
(produce synthetic climate series based on core statistics to examine extremes)
- ESM subsets
(to eliminate heavily biased models and/or focus resources)
- Climate emulators (e.g., MAGICC, HECTOR)
(reduced form representation of models for integrated assessment models)

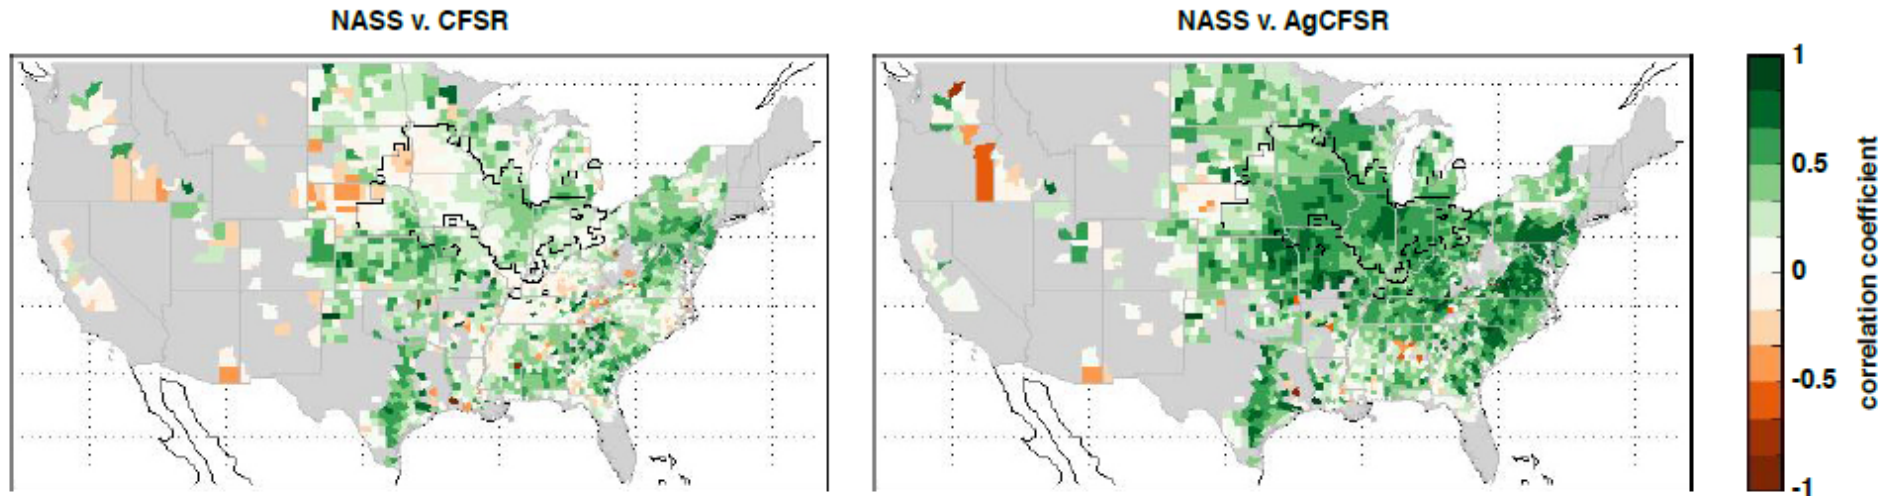

Multi-model mean annual biases for Temperature (left) & Precipitation (right) (Flato et al., 2013)

Bias-correction also often needed for Reanalysis

Many “climate forcing datasets” used for impacts research

Glotter et al. (2016) improvements in simulation of corn:

Above: 1980-2010 Correlations between National Agricultural Statistics Service (NASS) County-level production and that simulated by pDSSAT using CFSR (left) and AgCFSR (right) climate data (from Glotter et al., 2016). Note dramatic improvement in correlations over major agricultural regions including the US Corn Belt (outlined in black).

AgCFSR features bias corrections applied to CFSR for mean precipitation and temperature; diurnal Temperature Range, solar radiation, and number of rainy days

Selecting a Climate Scenario Approach

Depends on sector(s) examined

- Some can be considered as individual points (e.g., urban; single agricultural region; infrastructure)
- Some require spatial covariance across ESM gridcells (e.g., widespread extreme events; global food prices; basin water resources; species suitability; vector-borne diseases)
- Multi-disciplinary studies must target most needy applications (may lower quality of individual sectors assessments)

Climate scenario detail only useful if impact model/analysis is responsive

- Depends heavily on quality of impacts model
- Often less concerned with energy and water budget closure
- Off-season biases may not matter
- Many sub-seasonal characteristics only matter on aggregate unless extreme threshold surpassed
- Likewise, changes in highly uncertain variables can swamp more certain information (e.g., changes in downward SW radiation at the surface could dominate agricultural responses)

Many approaches -- nearly all seek to impose climate changes on observed conditions

(beware big %changes from dry GCM month imposed on wet observations)

Selecting a subset of models

Ideally we could find top performing models by filtering out those performing poorly
Paraphrasing Dennis Lettenmeier – “once you start eliminating models eventually you have none”

Subset to create more accurate weighted projections (e.g., Giorgi and Mearns, 2002)

- Often based on historical simulation performance for a key metric

Subset to conserve resources for other parts of impacts assessments

Selected GCMs determined by some combination of:

- Availability
 - CMIP outputs with desired variables
 - CMIP outputs with bias correction applied (BCSD, NEX, ISIMIP)
- Performance in key atmospheric phenomenon (e.g., monsoons)
- Equilibrium Climate sensitivity
- Spatial resolution
- Reputation of models and modeling groups (publication and inclusion in past CMIPs)
- Representation of broader ESM ensemble in region of interest

Resource Constraints for Regional Integrated Assessment of Future Agricultural Systems

29 Climate Models
~150 farms
2 crop models
4 crop/livestock species
2 future scenarios
2 adaptation packages
30 year simulations

=====

➤ > 4 million simulated years

Lots of pressure to reduce climate models in order to focus on future policies and adaptations

Subset example for Regional Integrated Assessment of Future Agricultural Systems (Ruane and McDermid, 2017)

**Ames, Iowa –
Climate Model
Projections and
subset selection for
Corn Season**

Fig. 1 Basic definition of the quadrants and Ames, Iowa, Maize season examples from 29 GCMs for Mid-Century RCP8.5. Each triangle is colored by its quadrant and represents one of the 29 GCMs, and the square represents the baseline condition (no change from observed average of 20.2 °C and 3.7 mm/day). Dots represent the mean of GCMs within any given quadrant, and the selected representative GCMs are denoted with a gray outline

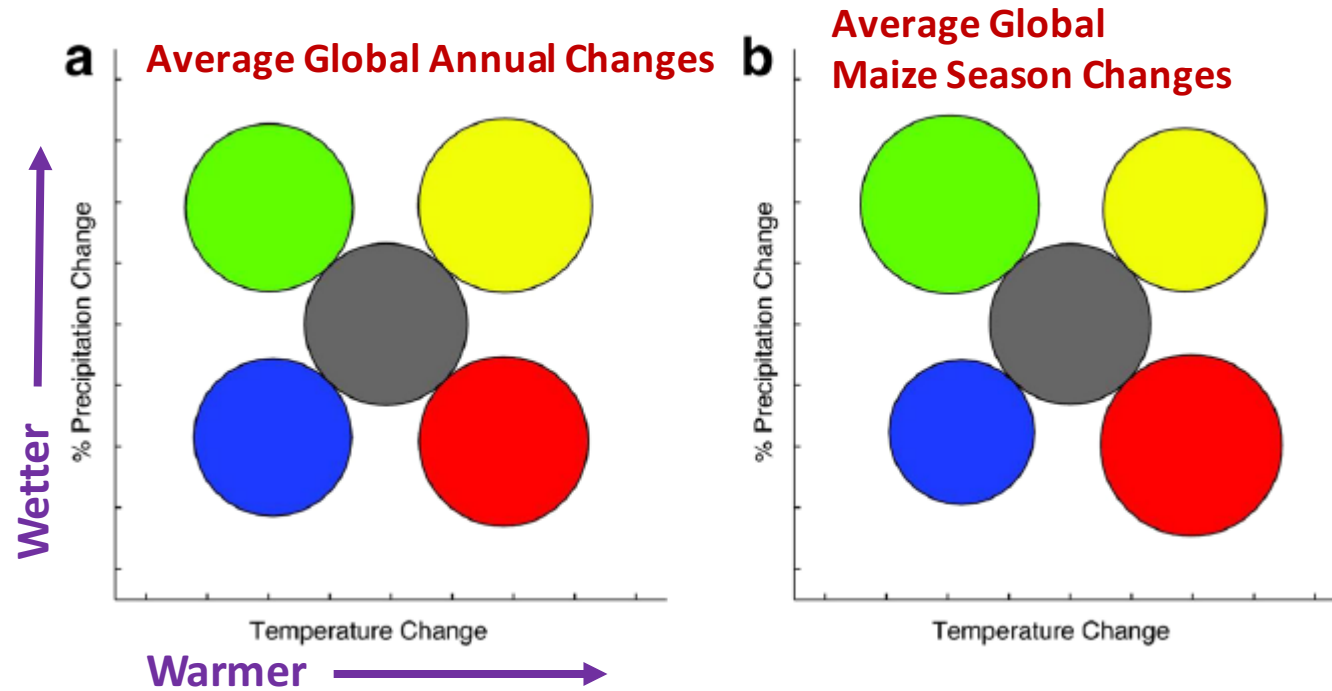

Subset example for Regional Integrated Assessment of Future Agricultural Systems (Ruane and McDermid, 2017)

Ames, Iowa – Model mean conditions in historical simulation

No strong connection between future quadrants or selected model and historical bias

Skewness in ensemble spread (Ruane and McDermid, 2017)

Projections for Maize season skew toward cool/wet and hot/dry axis

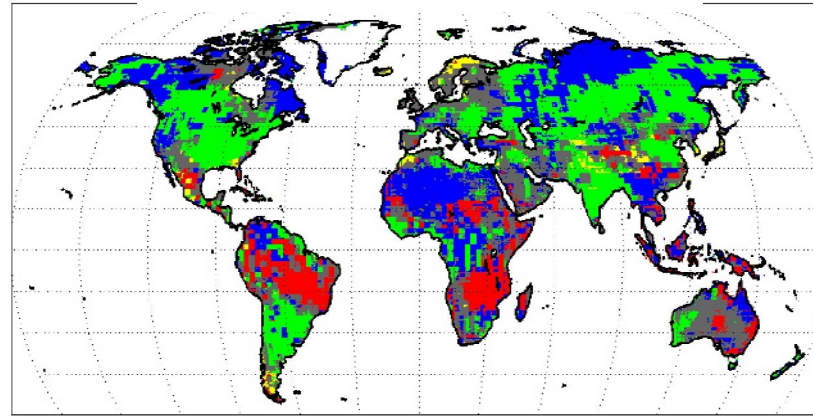

Size of circle represents fraction of models in each quadrant

GCM location amidst ensemble is fairly robust

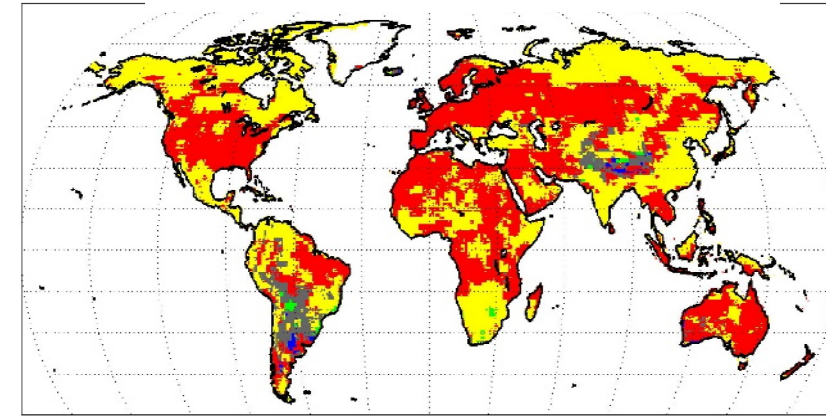

(Ruane and McDermid, 2017)

Atlas of relative GCM projections for T and P (Ruane and McDermid, 2017)

Priority Evaluation Requests

VIACS researcher priorities:

Regional patterns, seasonal progression and monsoons

- Evaluate ESMs in key circulation patterns (e.g., Sperber et al., 2013, for monsoons)
 - Onset, withdrawal, total precipitation, spatial extent, false starts, and break periods
- Connects with local interests and phenology

Modes of variability

- Less concerned about predictability of individual modes, more interested in overall distribution of extreme events (return periods)

Enhanced evaluation of extreme events

- Metrics of duration, frequency, extent, magnitude of extremes (SREX)
- Low-frequency outputs of high-frequency variables

Regime shifts

- When is future so different than present that our scenario generation or bias-correction methods break down? (e.g., rainy season shifts dramatically; massive land-surface or vegetation change)

A photograph of terraced rice fields. The terraces are filled with green rice seedlings. In the foreground, there is a large patch of corn plants. Three people are visible in the middle ground, working in the rice fields. The background shows a dense forest on a hillside.

Key Challenges for ESM-VIACS Connections

Key challenges for ESM-VIACS Connections

Improved VIACS models and analyses to make use of improved outputs

Incorporate offline VIA results for ESM development

- Benchmarking of global crop models and vegetation models' croplands (Müller et al., 2017)
- Review of agricultural land representation in ESMs (McDermid et al., in press)

ESM expert guidance and VIACS translation needed:

- Do we eliminate models for any purposes?
- How to handle requests that require output variables we do not trust?
(e.g., sea-level rise in AR5 without ice sheet dynamics;
solar radiation changes; localized extreme events)

Technical facilitation:

- Output access and processing for those with limited resources
- Interactive exploration of potentially huge number of tailored metrics that will be requested

Suggestions to Better Serve VIACS Applications and Downstream Stakeholders

Suggestions to Better Serve VIACS Applications and Downstream Stakeholders

- Produce low-frequency outputs of high-frequency statistical quantities
 - Facilitates large initial condition ensembles to explore internal variability
 - Daily histogram values for temperature and precipitation (*and perhaps RHmin*)
 - Hourly values for extreme thresholds (hot, cold, and wet)
 - Likely more efficient to count in model rather than post-process due to huge amount of output that would be required
- Online data holdings and workflows to facilitate access where computational resources are limited (ESMValTool, PMP, FACE-IT)
 - Common post-processing (e.g., regridding)
 - Ideally could allow customizable metrics (e.g., growing degree days with specified base temperature; number of extreme heat events in specified growing season; percentage of total precipitation falling in heaviest 5% of events)
- “Consumer reports” for ESMs listing known, VIACS-relevant biases
- Demonstration papers for CMIP6 MIPs: VIACS leader and MIP leader model application
- Version guidance:
 - Which versions/simulations are promoted for projection?
 - Which were included for diagnostic purposes

Thanks!

AgMERRA: Historical Climate Dataset for Agricultural Model Applications

Ruane et al., 2014

AgMERRA (1980-2010) features:

- Temperature and rainfall bias correction
- Improved solar radiation (NASA/GEWEX SRB)
- Improved precipitation variability (MERRA-land)
- Fine spatial patterns of rainfall from satellites
- An adjustment to diurnal temperature range
- Relative humidity at Tmax

AgMERRA better captures rainfall distribution and actual sequence of extreme events

Climate Scenarios Methods

Nearly all connect climate changes to observed conditions while de-emphasizing mean biases

Scenario generation approaches require core sets of outputs:

- **Delta method** (monthly mean changes imposed on observed time series)
- **Stretched distributions** (adjust observed distribution to impose mean and variability changes)
- **Quantile mapping** (adjust model distribution to better reflect observed characteristics)
- **Spatial disaggregation** (use high-resolution information to estimate finer spatial patterns)
- **Constructed analogues** (use large-scale conditions to identify historical proxies)
- **Trend-maintaining quantile mapping** (ISIMIP)

New developments and approaches frequently developed

Simple Climate Scenario Generation

(a) RCP8.5 mid-century temperature scenarios for all GCMs

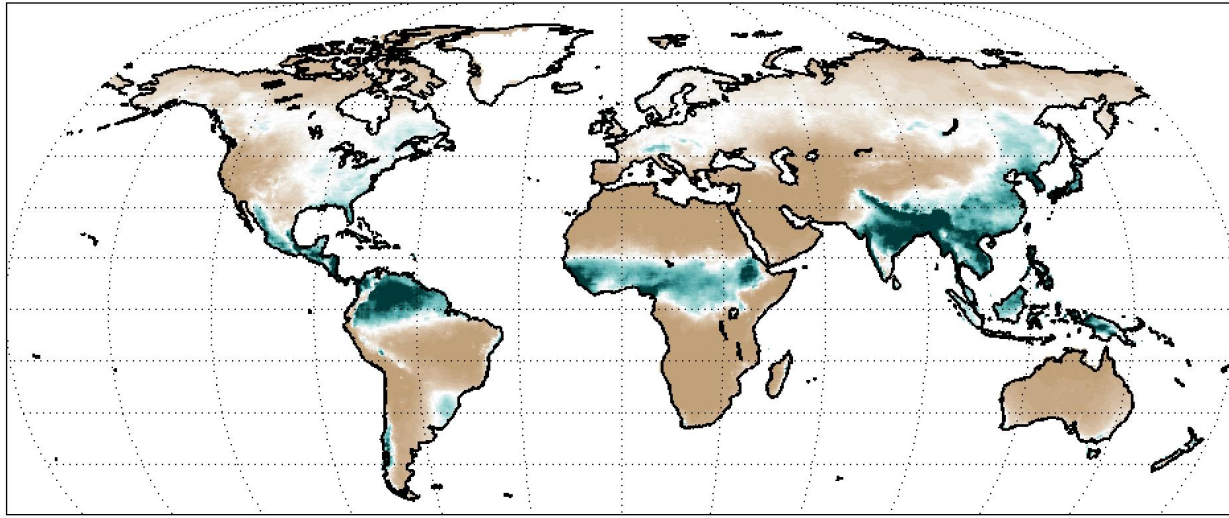

(b) RCP8.5 mid-century precipitation scenarios for all GCMs

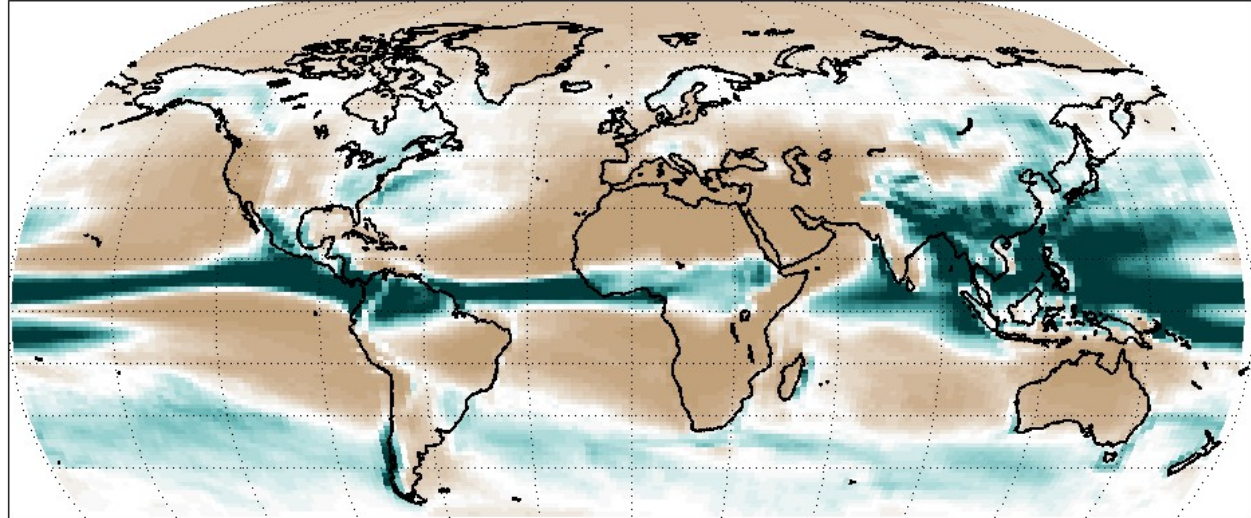

Monsoons

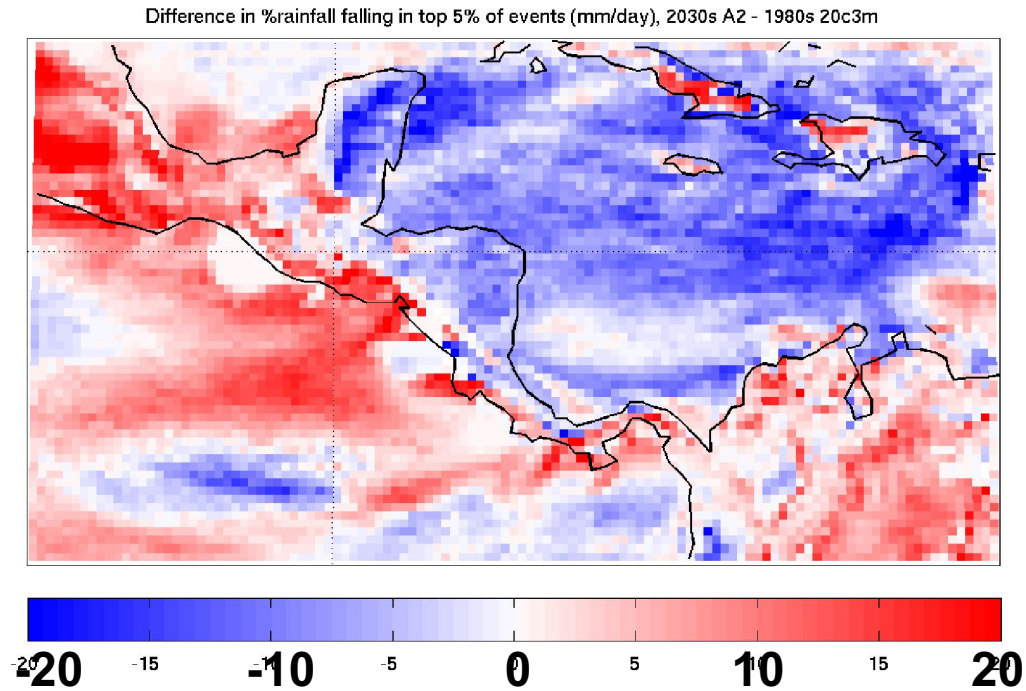

AgMERRA 1980-2009 Mean July Precipitation

HadGEM2-ES1980-2009 Mean July Precipitation

Extreme rainfall patterns changing

- **Shifts in the percentage of rainfall falling in rainiest 5% of days**
- **Areas with decreasing rainfall and increased extreme characteristics are vulnerable**

(Ruane et al., as yet unpublished)

NPCC2 Quantitative Extreme Event Projections (Horton et al., 2015)

| | | | 2020s | | | 2050s | | |
|------------------------------------|---|-------------------------|--------------|--------------|---------------|--------------|--------------|---------------|
| | | Baseline (1971-2000) | Low-estimate | Middle range | High-estimate | Low-estimate | Middle range | High-estimate |
| Heat waves and cold weather events | Number of days/year with maximum temperature at or above 90°F | 18 | 24 | 26 to 31 | 33 | 32 | 39 to 52 | 57 |
| | Number of heat waves/year | 2 | 3 | 3 to 4 | 4 | 4 | 5 to 7 | 7 |
| | Average heat wave duration (in days) | 4 | 5 | 5 to 5 | 5 | 5 | 5 to 6 | 6 |
| | Number of days/year with minimum temperature at or below 32°F | 72 | 50 | 52 to 58 | 60 | 37 | 42 to 48 | 52 |
| Intense Precipitation | Number of days/year with rainfall at or above 2 inches | 3 | 3 | 3 to 4 | 5 | 3 | 4 to 4 | 5 |

Based on 35 GCMs and two Representative Concentration Pathways. Baseline data are from the National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center (NCDC) United States Historical Climatology Network (USHCN), Version 2 (Menne et al., 2009). Shown are the low-estimate (10th percentile), middle range (25th percentile to 75th percentile), and high-estimate (90th percentile) 30-year mean values from model-based outcomes. Heat waves are defined as three more consecutive days with maximum temperatures at or above 90°F.

Corn Sensitivity to Climate Variability Changes

- Use stretched distribution approach to impose particular statistical qualities on observed series
- Solid lines include interactions between changes in mean and variability
- Note that as alpha parameter decreases, rainfall is more extreme.

(Ruane et al., as yet unpublished)
