

Atmospheric response to sea ice: the importance of coupling and the background state

Doug Smith, Nick Dunstone, Adam Scaife, Emma Fiedler, Dan Copsey
and Steven Hardiman

Imposed Arctic sea ice change

(a) : JJA

(b) SON

(c) DJF

(d) MAM

- 30 year period Dec 1979 to Nov 2009
- CONTROL: observed sea ice (monthly mean)
- PERTURBED: reduced sea ice, obtained by projecting recent 15 year trends
- HADGEM3, GA3, ~150 km resolution, 85 levels
- 10 ensemble members
- AMIP, observed SST, set to 0°C where sea ice has disappeared
- Also COUPLED (1° ocean resolution, 75 levels):
 - same sea ice as AMIP
 - upper 200m ocean is free to respond
 - constrained below 200m to prevent spurious circulations

Met Office
Had

Surface temperature response

AMIP

(a) AMIP : JJA

(b) SON

(c) DJF

(d) MAM

COUPLED

(e) CPLD : JJA

(f) CPLD : SON

(g) DJF

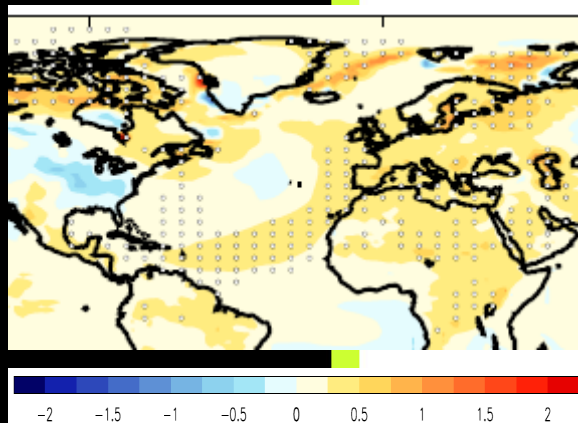

(h) MAM

- Warming where sea ice reduced
- Bigger in COUPLED model, and extends to surrounding ocean

Remote response in CPLD (JJA)

Temperature

Rainfall

Zonal wind: Atlantic (90W to 0E)

- Warm tropical Atlantic (only in coupled simulations)
- Anomalous Hadley circulation northward shift of ITCZ
 - increased rainfall (including Sahel)
 - Increased ascent and reduced zonal wind shear → more hurricanes
- See also Chang and Bitz 2005

Sea level pressure response

Met Office
HadGEM2-ES

AMIP

(a) AMIP : JJA

(b) SON

(c) DJF

(d) MAM

COUPLED

(e) Coupled : JJA

(f) SON

(g) DJF

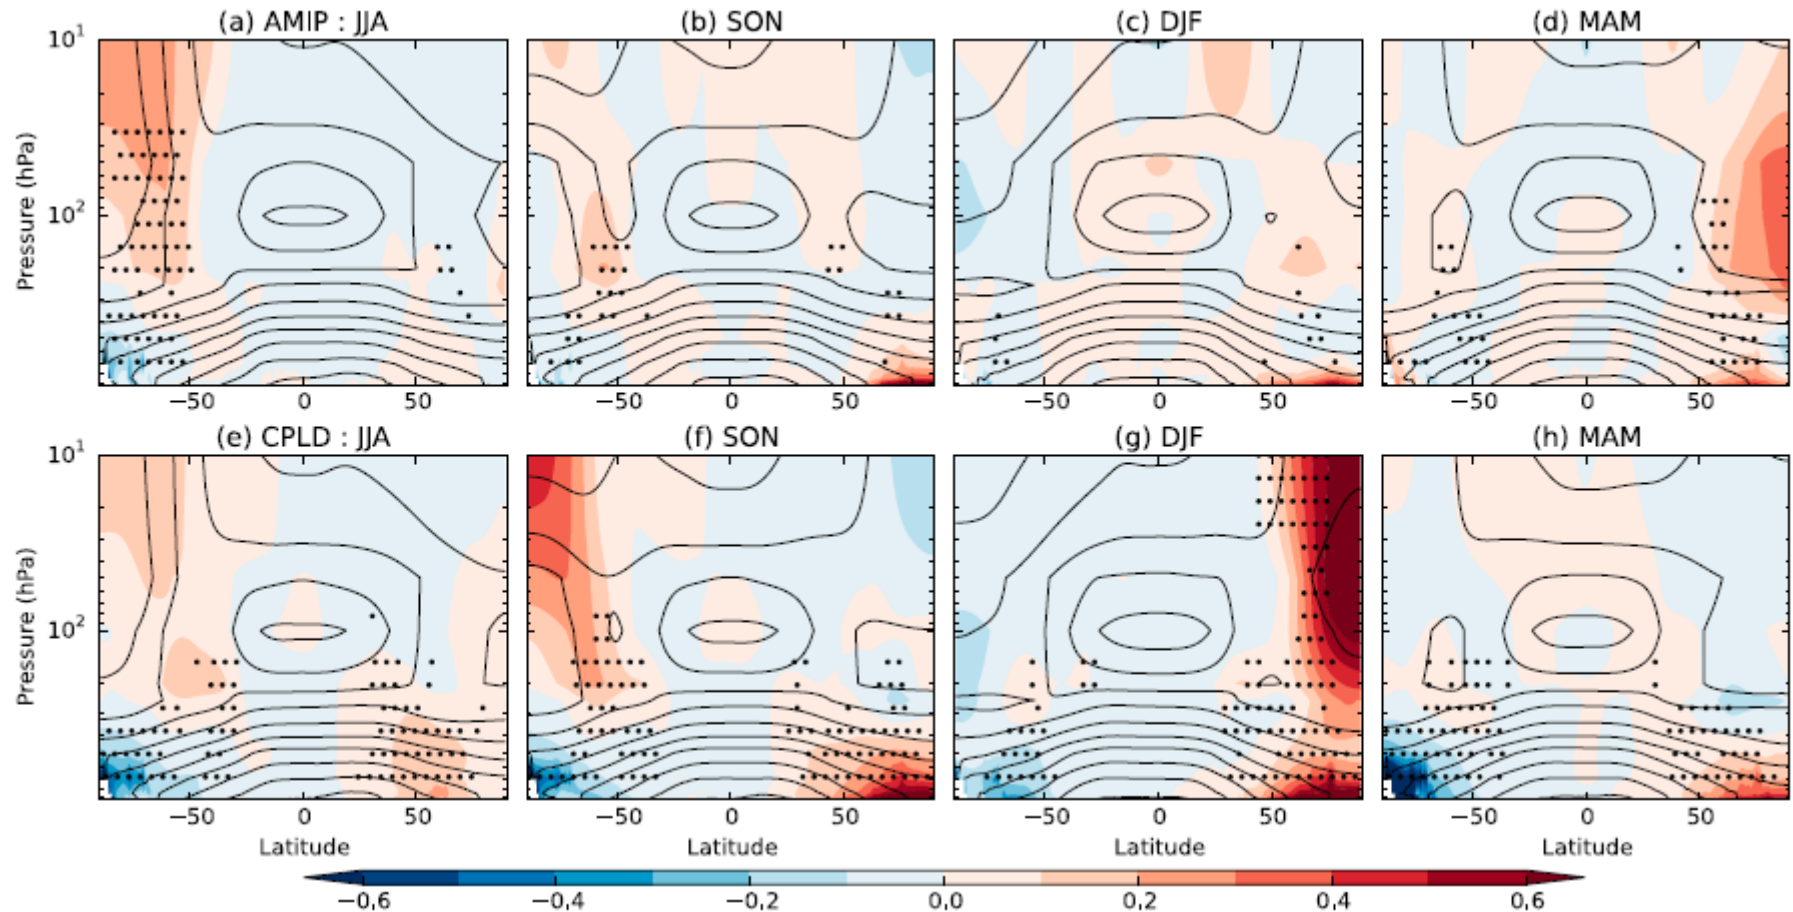

(h) MAM

- AMIP: “heat low” in all seasons → projects onto +ve NAO
- COUPLED: similar in JJA and SON though larger signal
- Opposite signal (-ve NAO) in DJF and MAM

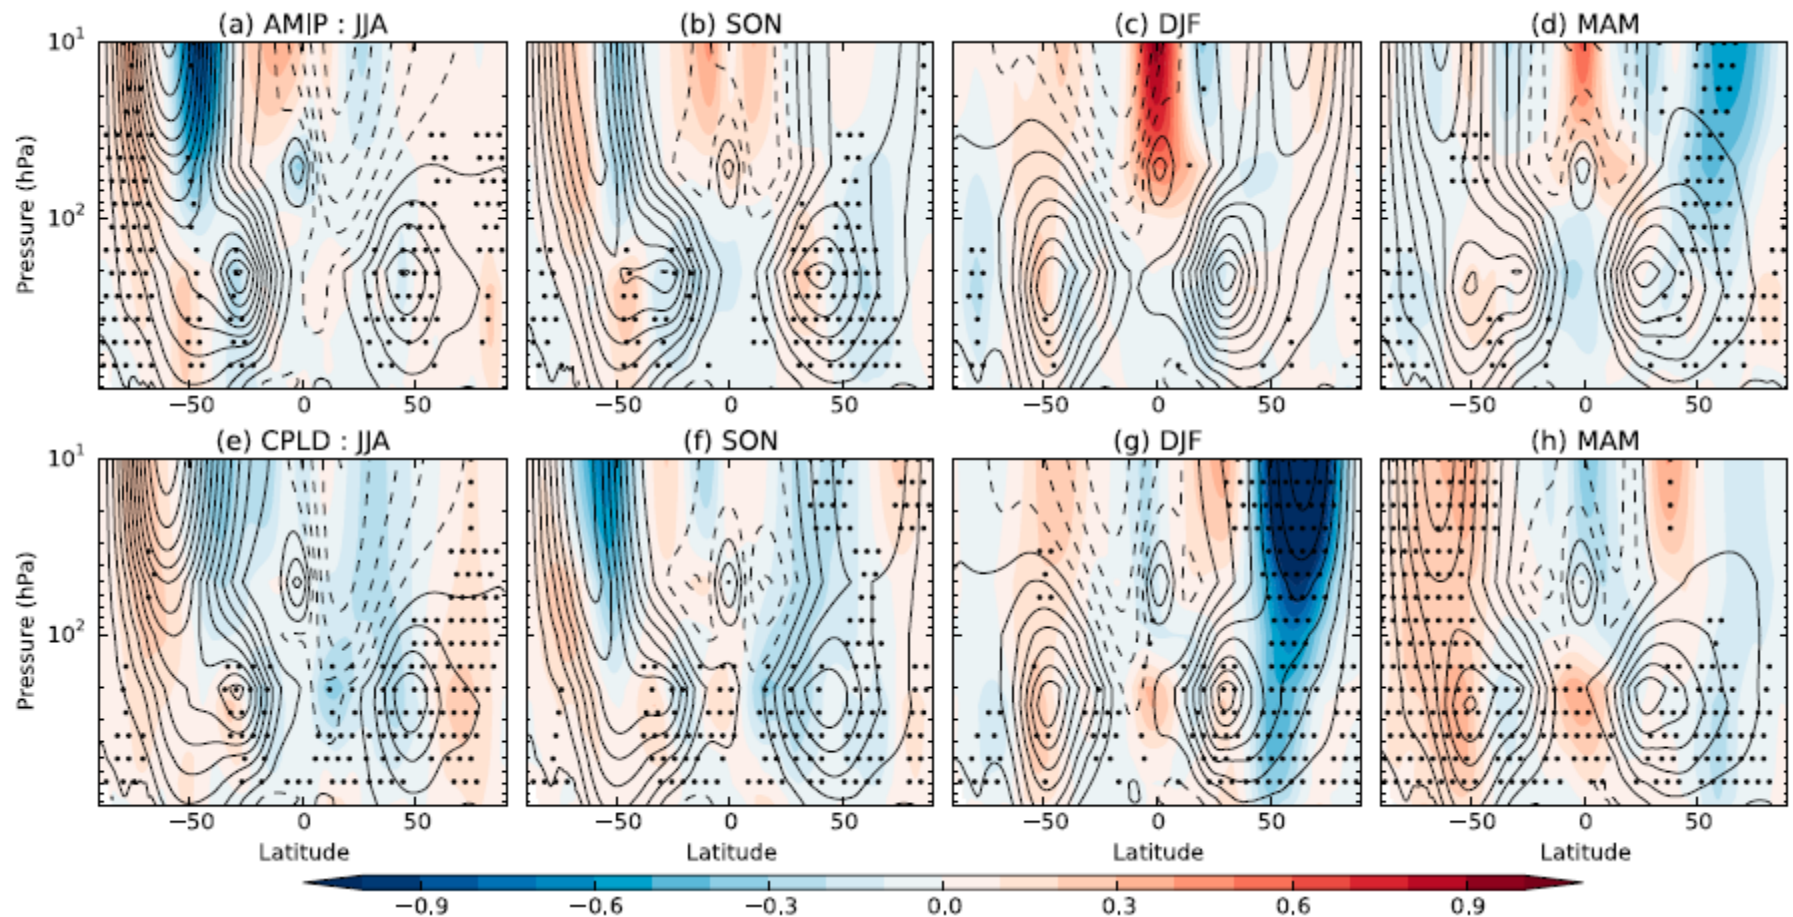

Zonal mean temperature response

- AMIP: Arctic warming confined to boundary layer (except MAM)
- COUPLED: Arctic warming throughout atmosphere

Zonal mean wind response

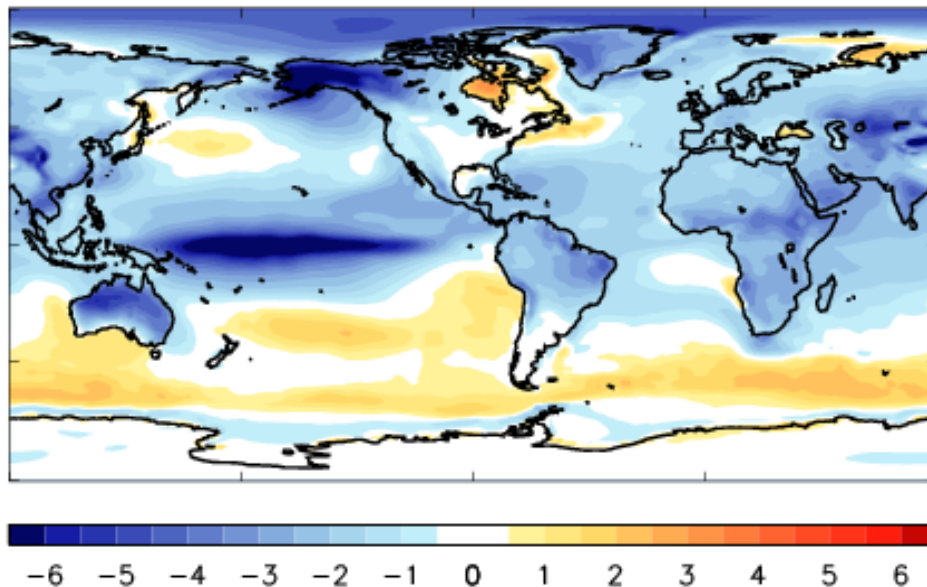

- AMIP: Little response in DJF
- COUPLED: Barotropic response, weakening and Equatorward shift of the jet

Met Office
Hadley Centre

COUPLED model biases

(a) CPLD-AMIP temperature

(b) CPLD-AMIP zonal wind

(c) AMIP_CPLD-AMIP zonal wind

- Different response could be caused by coupling or background state (model bias)
- Test by repeating AMIP but imposing COUPLED SST bias → AMIP_CPLD
- Reproduces zonal wind biases

Met Office
Hadley Centre

Sea level pressure response depends on background state

COUPLED

AMIP_CPLD

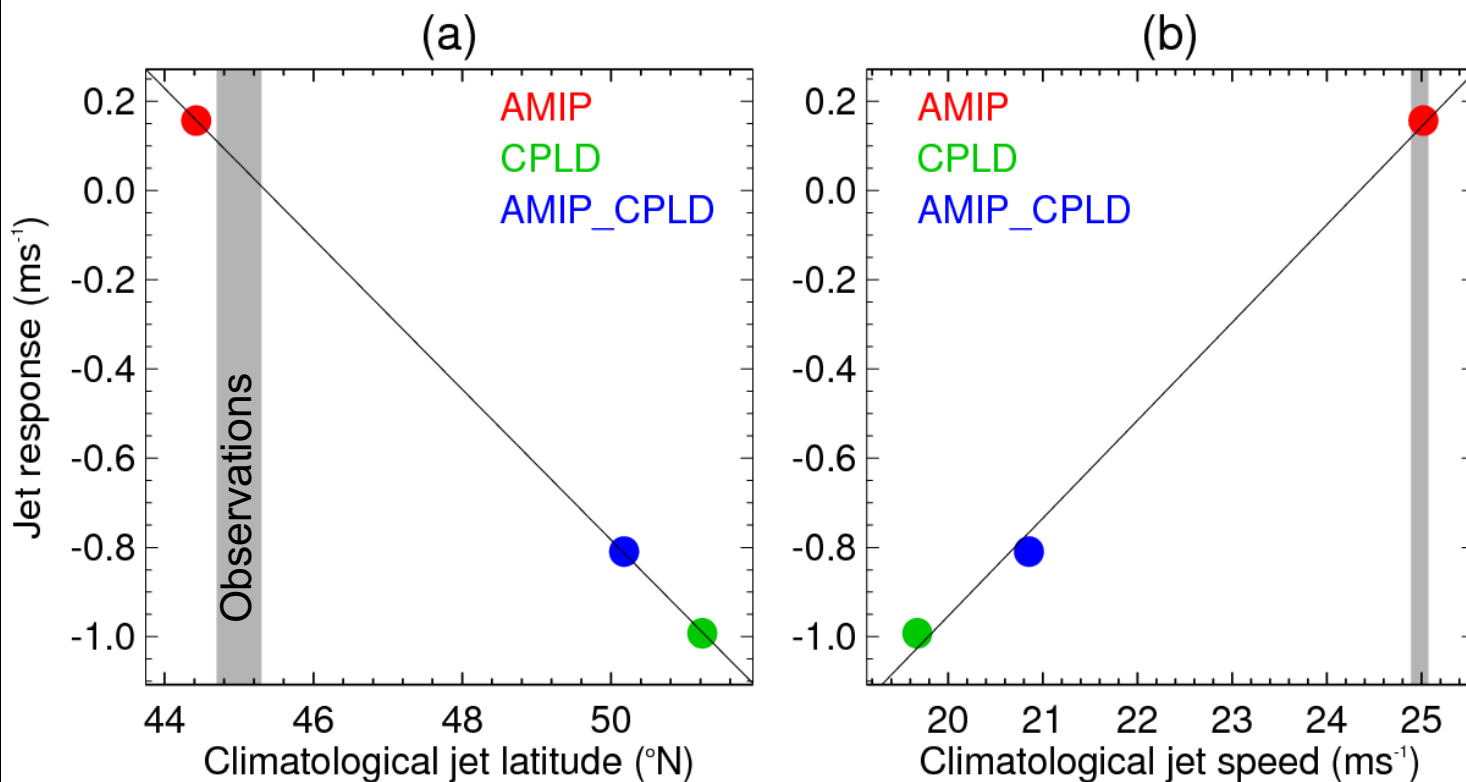

- COUPLED model response reproduced by AMIP_CPLD
- Background state is key

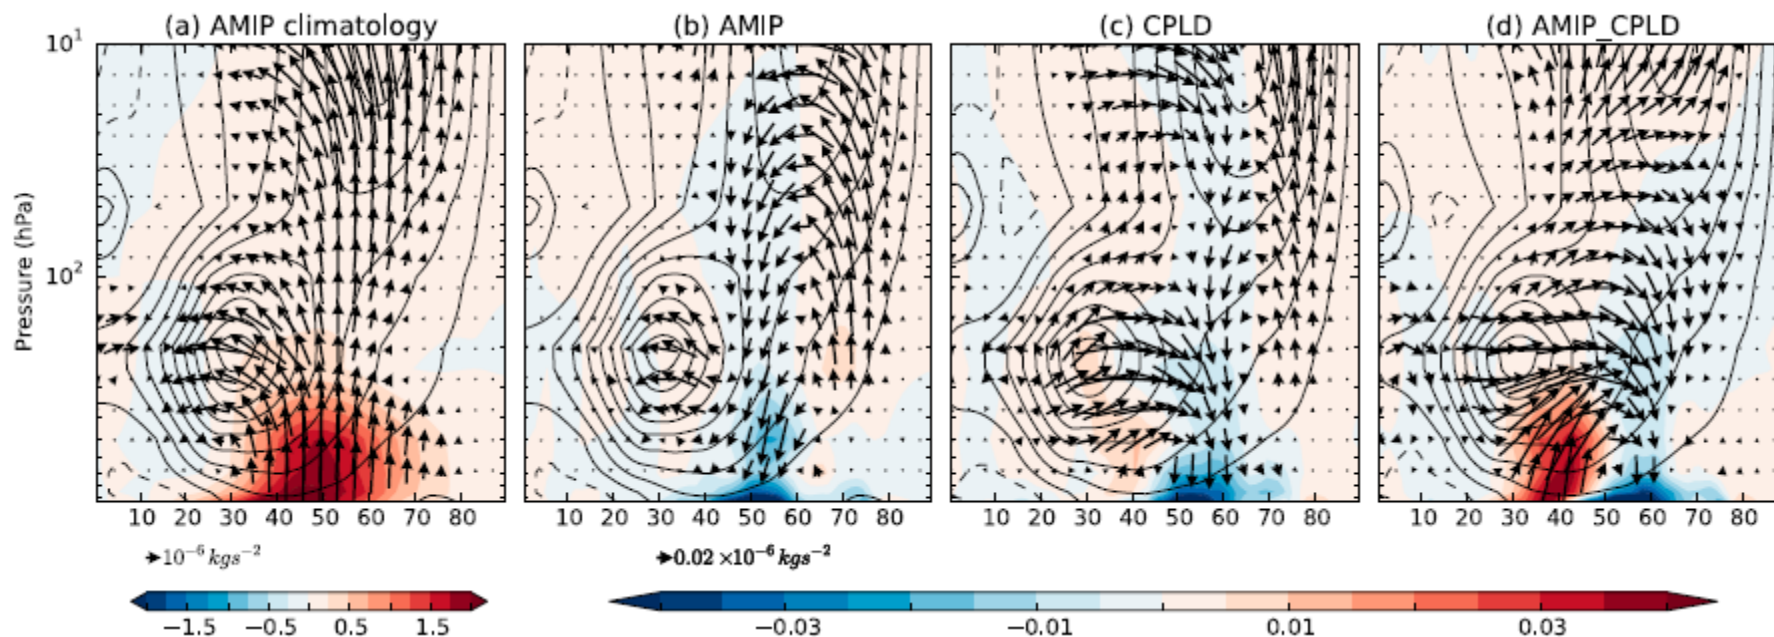

Met Office
Hadley Centre

Response depends on Atlantic jet?

- Stronger weakening of jet if jet is more poleward
- ...or weaker
- AMIP is closest to observations (grey shading)

EP flux response (upward)

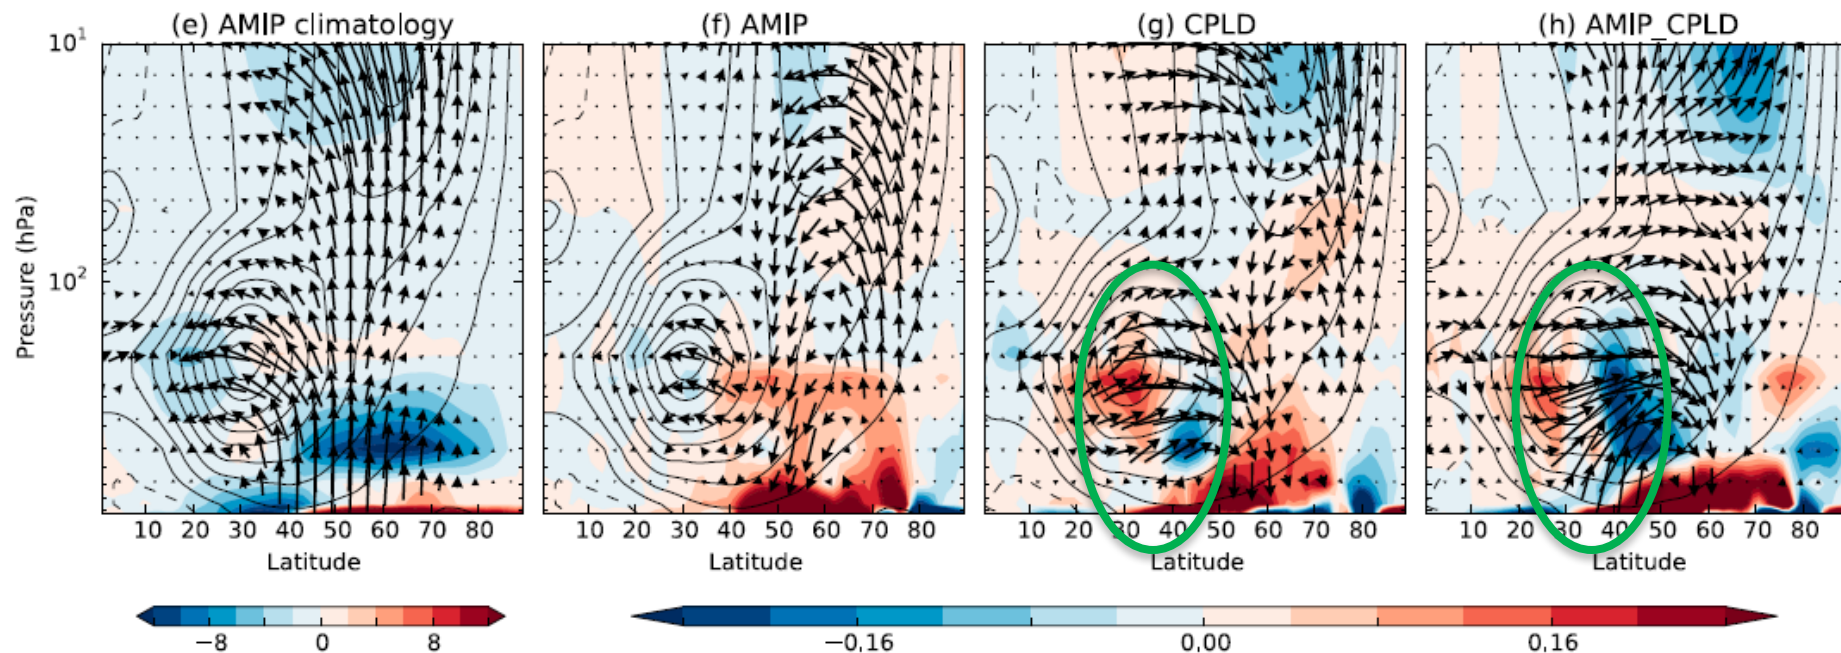

- Reduced upward EP flux in all experiments (in contrast to many studies)
- Consistent with reduced Equator to pole temperature gradient

Met Office
Hadley Centre

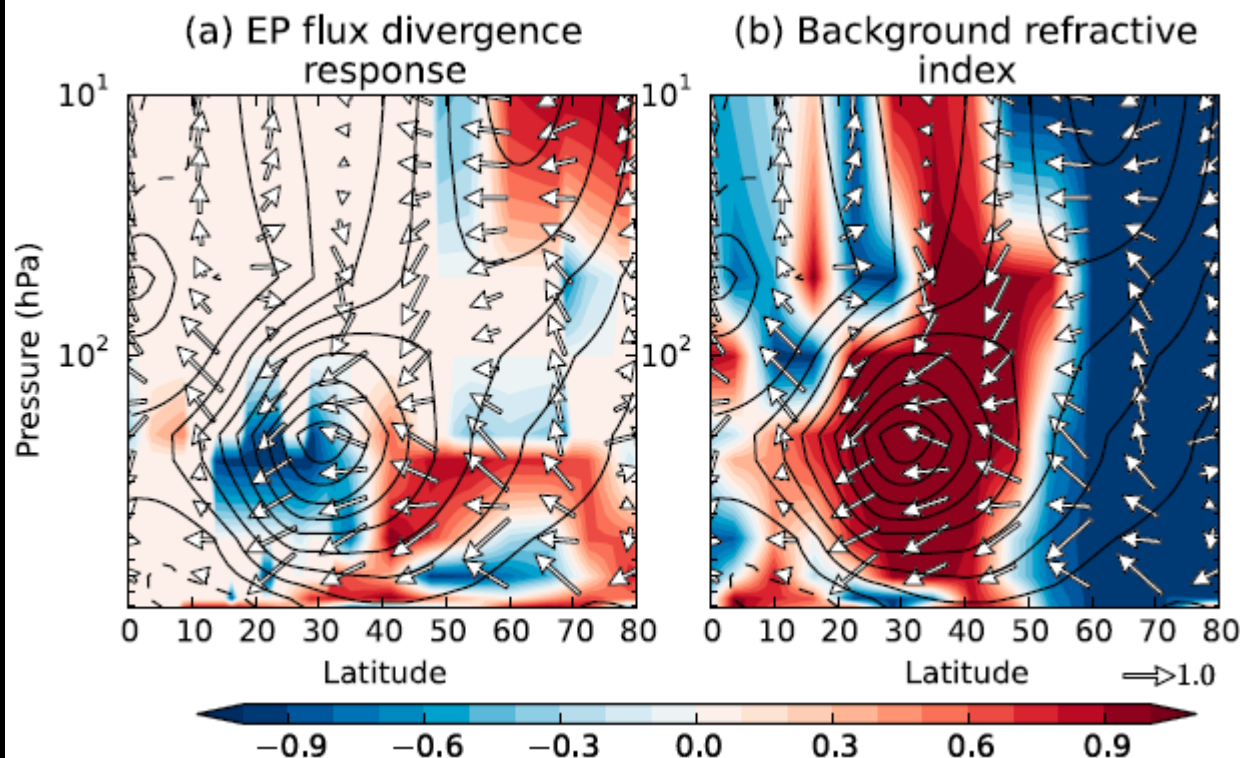

EP flux response (divergence)

- CPLD and AMIP_CPLD: EP flux divergence (convergence) on equatorward (poleward) flank of jet
- Southward shift, -ve NAO

Role of refractive index

Correlation across AMIP, CPLD and AMIP_CPLD of jet response to *increased* sea ice

Easier to visualise response to *increased* sea ice

- Increased wave flux
- Propagation depends on climatological refractive index
- EP flux divergence (convergence) on poleward (equatorward) flank of jet
- Poleward shift of jet, +ve NAO

Constraint based on refractive index

- Response depends on wave propagation, and hence refractive index (difference between mid (25-35°N) and high (60-80°N) latitudes at 200 hPa)
- Observations (grey shading) closer to CPLD than AMIP, supporting -ve NAO response
- Need more models → coordinated multi-model experiments (PA-MIP)

Met Office
Hadley Centre

Caution: response cannot be diagnosed by regression

(a) Obs regression

(b) AMIP regression

(c) AMIP response

- Regression between autumn (SON) sea ice extent and winter (DJF) sea level pressure (sign reversed)
- Obs and AMIP agree
- BUT AMIP response to reduced sea ice is completely different

Summary

- Coupling enables remote SST response → Atlantic ITCZ and **Sahel rainfall, hurricanes**
- Sign of NAO response to Arctic sea ice depends on the climatological background (e.g. **model bias**)
- Reduced sea ice results in **reduced upward wave flux** (in contrast to several other studies)
- Response depends of the background **refractive index** (difference between mid and high latitudes in upper troposphere)
- Constraint based on refractive index supports –ve NAO
- But more models needed (**PA-MIP**)
- CAUTION: response **cannot be diagnosed from regression** (and hence from observations alone)
